Cyber-physical systems

Cyber-physical systems are the integration of computational devices with physical processes: embedded computers monitor and control physical processes, which in return affect computations through information feedback loops.

Challenges when developing CPS:

- CPS models are heterogeneous. The continuous behavior is described by differential equations, while the discrete behavior is formalized with finite-state automata frameworks.
- Complex control objectives. Reachability, fault-tolerance, LTL formulas etc..

Finite Transition System. Safety Specification

A finite transition system (FTS) is a tuple $\Sigma = (O, U, E)$ consisting of

- $\Sigma = (Q, U, F)$, consisting of
 - \blacksquare a finite set of states Q.
 - $Q = \{q_{us}, q_1, q_2 \dots, q_{15}\}$
 - a finite set of inputs U. $U = \{u_1, u_2, u_3, u_4\}$
 - transition relation $F \subseteq Q \times U \times Q$. $(q, u, q') \in F \Leftrightarrow q' \in F(q, u)$

A state $q \in Q$ is blocking if $F(q, u) = \emptyset$ for any $u \in U$.

A trajectory is a finite or infinite sequence of transitions $q_0 \xrightarrow{u_0} q_1 \xrightarrow{u_1} \ldots$, s.t. $q^i \in Q, u^i \in U$ and $q^{i+1} \in F(q^i, u^i)$ for all $i \ge 0$.

Safety specification: Safe set $Q_S \subset Q \Rightarrow$ Unsafe set $Q \setminus Q_S$. $Q_S = \{q_1, q_2, \dots, q_{15}\} \Rightarrow Q \setminus Q_S = \{q_{us}\}.$

FTS. Maximal Safety Controller

A controller is a map $C: Q \to 2^U$, such that $C(q) \subseteq En_F(q)$ for every $q \in Q$, where $En_F(q) = \{u \in U \mid F(q, u) \neq \emptyset\}$.

A safety controller *C* is a controller such that

- Dom(C) ⊆ Q_s , where Dom(C) = { $q \in Q | C(q) \neq \emptyset$ }.
- for all $q \in \text{Dom}(C)$ and for all $u \in C(q) \Rightarrow F(q, u) \subseteq \text{Dom}(C)$.

There is a unique maximal safety controller C^* such that for any safety controller C

■
$$\mathsf{Dom}(C) \subseteq \mathsf{Dom}(C^*).$$

■ for all $q \in \mathsf{Dom}(C), C(q) \subseteq C^*(q).$

The set of safely controllable states is a set $Cont(\Sigma, Q_S) = \{q \in Q \mid q \in Dom(C^*)\}.$

Drawbacks of Classical Synthesis Procedure

Classical Synthesis Approach

- The symbolic model is required to be precomputed before the synthesis.
- Brute-force exploration of the finite transition system.

Lazy Synthesis Approaches

- The abstraction is computed on-the-fly, during the synthesis procedure.
- Only essential for synthesis part of abstraction is explored.

|--------------|----------------|---------------------------|-------------------------|------------------|
| Adaptive Cr | uise Control. | Simulation Results | | |

We have implemented classical synthesis approach and lazy synthesis approach for a multi-scale time-sampling abstraction.

In both cases, the controllable domains (right figure) for a given safe set (left figure) coincide. However, lazy approach is 2.58 times faster than the classical one since it explores 19574 less states.

| Introduction | Classical ABCS | Lazy Synthesis Approaches | Interval Approximations | Conclusion |
|--------------|----------------|---------------------------|-------------------------|------------|
| | | | | |

Adaptive Cruise Control. Simulation results

We also simulated a closed-loop trajectory for a given disturbance realisation F_1 .

The closed-loop trajectory satisfies the safety restriction and shows a nice behavior in terms of stability.

Monotone Systems and Lower-closed Safety Specification

If a transition system is monotone then for all states $q_1 \preceq_Q q_2$, inputs $u_1 \preceq_U u_2$ we have $F(q_1, u_1) \subseteq \downarrow F(q_2, u_2)$. A finite lower closed set can be represented by its basis¹.

Lazy Computation of Maximal Safety Controller

- Non-deterministic transition system is replaceable by deterministic one¹.
- Control domain can be computed by the iterative exploration of the basis, while using only the lower priority inputs.
- We can repeat the similar procedure to find a maximal safety controller

¹E. S. Kim, M. Arcak, and S. A. Seshia (2016). Directed Specifications and Assumption Mining for Monotone Dynamical Systems. HSCC.

Let a set of inputs $U = [u_{min}, u_{max}]$, a disturbance set $W = [w_{min}, w_{max}]$, and there is a total order on input space $u_{min} = u_1 < u_2 < \ldots < u_N = u_{max}$.

- Non-deterministic transition system is replaceable by deterministic one¹.
- Control domain can be computed by the iterative exploration of the basis, while using only the lower priority inputs.
- We can repeat the similar procedure to find a maximal safety controller

Illustrative example. Adaptive cruise control

Two cars move along a straight road. The acceleration F_1 of the fist car is a disturbance, the acceleration F_2 of the second is a controlled parameter.

Each car is modeled as a point mass

 $m_i \dot{v}_i = F_i - (a + bv_i + cv_i^2), \ i = 1, 2.$

Both cars respect the speed limitations:

$$v_i \in [0, v_{max}], i = 1, 2.$$

Disturbance: $F_1 \in [-0.3m_1g, 0.2m_1g]$.

■ Control: $F_2 \in [-0.3m_2g, 0.2m_2g]$.

| Mixed Monc | tone Function | S | | |

A function $f : \mathbb{R}^n \to \mathbb{R}^m$ is said to be mixed-monotone, if there exists $g : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^m$ satisfying the following:

- for all $x, \hat{x} \in \mathbb{R}^n$ such that $x \leq \hat{x}$ the following holds $g(x, y) \leq g(\hat{x}, y)$ for all $y \in \mathbb{R}^n$;
- for all $y, \hat{y} \in \mathbb{R}^n$ such that $y \leq \hat{y}$ the following holds $g(x, y) \succeq g(x, \hat{y})$ for all $x \in \mathbb{R}^n$.

A function g satisfying the above conditions is called a decomposition function of f.

Decomposition function g is called tight if for all $\underline{x}, \overline{x} \in \mathbb{R}^n$ s.t. $\underline{x} \preceq \overline{x}$, $[g(\underline{x}, \overline{x}), g(\underline{x}, \overline{x})]$ is the smallest interval that contains $\{f(x)|x \in [\underline{x}, \overline{x}]\}$. That is

$$[g(\underline{x},\overline{x}),g(\underline{x},\overline{x})] = [\inf_{\xi \in [\underline{x},\overline{x}]} f(\xi), \sup_{\xi \in [x,\overline{x}]} f(\xi)].$$

| Tiaht Decc | pmposition Fi | unctions | | |

Let for all $x, y \in \mathbb{R}^n$ and $h: \mathbb{R}^n \to \mathbb{R}^n$, define

$$opt_{\xi}^{(x,y)}h(\xi) = \begin{cases} \inf_{\xi \in [x,y]} h(\xi), & \text{if } x \le y \\ \sup_{\xi \in [y,x]} h(\xi), & \text{if } x > y \end{cases}$$

Theorem[1]. Let $f : \mathbb{R}^n \to \mathbb{R}^m$ be such that $opt_{\xi_i}^{(x_i,y_i)}f(\xi_i)$ is well defined, then the following $g : \mathbb{R}^{2n} \to \mathbb{R}^m$ defined element-wise by

$$g_j(x, y) = opt_{\xi_1}^{(x_1, y_1)} opt_{\xi_2}^{(x_2, y_2)} \dots opt_{\xi_n}^{(x_n, y_n)} f_j(\xi), \quad j = 1, 2, \dots, m$$

is a tight decomposition function of f.

| | | | | |

Decomposition functions. Examples.

For $f(x_1, x_2) = x_1 + x_2$ the tight decomposition function $g(x, \hat{x}) = x_1 + x_2$.

For $f(x_1, x_2) = x_1 - x_2$ the tight decomposition function $g(x, \hat{x}) = x_1 - \hat{x}_2$.

For $f(x_1, x_2) = x_1 x_2$ the tight decomposition function

$$g(x, \hat{x}) = \begin{cases} x_1 x_2, \text{ if } x_2 \ge 0\\ \hat{x}_1 x_2, \text{ if } x_2 < 0 \end{cases} \text{ or } g(x, \hat{x}) = \begin{cases} x_1 x_2, \text{ if } x_1 \ge 0\\ x_1 \hat{x}_2, \text{ if } x_1 < 0 \end{cases}$$

We also can derive a decomposition function for f from taylor's approximations

$$g_{f}(x,\hat{x}) = \begin{cases} f(\hat{x}) + \sup_{z \in [\hat{x}, x]} \left(\sum_{i=1}^{n} \frac{(z-\hat{x})^{i}}{i!} f^{(i)}(\hat{x}) \right) + \frac{(x-\hat{x})^{n+1}}{(n+1)!} \sup_{z \in [\hat{x}, x]} \max(0, f^{(n+1)}(z)) & \text{if } \hat{x} \le x \\ f(\hat{x}) + \inf_{z \in [x, \hat{x}]} \left(\sum_{i=1}^{n} \frac{(z-\hat{x})^{i}}{i!} f^{(i)}(\hat{x}) \right) + \frac{(x-\hat{x})^{n+1}}{(n+1)!} \sup_{z \in [\hat{x}, x]} \max(0, f^{(n+1)}(z)) & \text{if } \hat{x} \ge x, n \text{ even} \\ f(\hat{x}) + \inf_{z \in [x, \hat{x}]} \left(\sum_{i=1}^{n} \frac{(z-\hat{x})^{i}}{i!} f^{(i)}(\hat{x}) \right) + \frac{(x-\hat{x})^{n+1}}{(n+1)!} \inf_{z \in [x, \hat{x}]} \min(0, f^{(n+1)}(z)) & \text{if } \hat{x} \ge x, n \text{ odd} \end{cases}$$

| | | | | |

Reachable Sets Over-approximations based on Mixed Monotonicity.

Theorem [1]. Given system $\dot{x} = f(x)$, where state $x \in X \subset \mathbb{R}^n$ and vector field *f* is defined on some open set X_e containing set *X*, assume that *f* is mixed monotone and is locally Lipschitz on X_e , the system is forward complete, and the domain *X* is positively invariant under the considered dynamics. Then, the flow map Φ_t is mixed monotone.

Let the initial set $X^0 = [\underline{x}^0, \overline{x}^0]$ is an interval, consider an embedding system system

$$\begin{aligned} & \dot{\overline{x}}_i = g_i(\overline{x}, \underline{x}), \quad \overline{x}_i(0) = \overline{x}_i^0 \\ & \underline{\dot{x}}_i = g_i(\underline{x}, \overline{x}), \quad \underline{x}_i(0) = \underline{x}_i^0 \end{aligned}$$

$$(1)$$

Then

$$\textit{Reach}(t, X^0) \subseteq [\underline{x}(t; [\underline{x}^0, \overline{x}^0]), \overline{x}(t; [\overline{x}^0, \underline{x}^0]].$$

| Introduction | Classical ABCS | Lazy Synthesis Approaches | Interval Approximations | Conclusion ●O |
|--------------|----------------|---------------------------|-------------------------|------------------|
| Conclusion. | Questions? | | | |

Abstraction-Based Synthesis Techniques

- abstraction-based methods allow to deal with hybrid dynamic of the systems and complex control objectives, but from a poor scalability.
- Iazy synthesis approaches computes the symbolic model on-the-fly, and avoid non-essential for synthesis purpose computations.
- the worst-case complexity of lazy approaches coincide with computational complexity of classical synthesis algorithm, but they are more efficient in practice.

Reachability Analysis

- is a core of abstraction-based synthesis techniques, formal verification, robust control model predictive control and other approaches with safety guarantees.
- we have to develop efficient approaches to compute accurate approximations.
